Discuss how secondary markets benefit issuers and investors.

The secondary markets provide liquidity to investors after their initial purchase of the security. This liquidity encourages them to purchase the security at the initial offer. The current market price also reflects current prospects for the firm and the competitiveness of the issue relative to similar securities. Corporate treasurers follow their stock's price closely because the stock price reflects how well their firm and the market are performing. The current security price also provides information about the cost of obtaining any additional funds.

How can brokers and dealers make money? Which activity is riskier? Why?

An asset broker assists buyers and sellers of securities by providing a mechanism for buyers or sellers to process their orders. If the broker assists one party in finding another party, the broker charges a small fee called a commission. An asset dealer buys the security for his or her own account at the bid price and then sells the security at a higher ask price. The dealer profits by earning the bid-ask spread or the difference between the buy and sell prices. The dealer's function is riskier because the dealer must maintain an inventory of the asset and honor quotes to buy and sell. If the security is risky, the value of the inventory can fluctuate with market prices. The broker takes less risk because he or she does not own the security.

What does an asset transformer do? Why is asset transformation a risky activity?

An asset transformer buys one security from a customer and makes or creates a separate claim in order to raise funds. For example, a bank accepts deposits and uses them to make loans. This is normally a risky activity because the asset acquired will be riskier than the security (or deposit) used to raise funds because the intermediary hopes to profit on the spread between the rate earned on the asset claim and the rate paid on the liability claim. In order for this spread to be positive, generally speaking, the asset must be riskier than the liability.

How can using indirect finance rather than direct finance reduce agency costs for users of funds that is associated with monitoring funds?

A large FI has a greater incentive to monitor the behavior of users of funds in indirect financing. The FI supposedly hires and trains experts who know how to collect information about a fund's user and evaluate whether the fund's user is acting appropriately. In direct finance, a fund user sells claims to the public at large. In this case, there is little incentive for an individual claim holder to monitor and attempt to enforce good behavior on the part of the fund's user. The benefit of monitoring and enforcement is shared among all claim holders, but the cost would be borne by the sole individual. This is termed the "free-rider" problem. If there is improved monitoring of borrower behavior, the problem of agency costs is likely to be reduced.

What have been the major factors contributing to growth in the foreign financial markets?

1. The amount of savings available for investment in foreign countries has increased.
2. International investors have looked to the United States and other markets for better investment opportunities.
3. The Internet has helped provide additional information on foreign markets and overseas investment opportunities.
4. Specialized intermediaries such as country-specific mutual funds have been developed to facilitate overseas investments.
5. The euro has had a notable impact on the global financial system by being an important currency for international transactions.
6. Deregulation of foreign markets has allowed many new investors to participate in international investing.

You are a corporate treasurer seeking to raise funds for your firm. What are some advantages of raising funds via a financial intermediary (FI) rather than by selling securities to the public?

Advantages include:

- Speed: Funds can normally be raised more quickly through FIs.
- Registration process/cost: The registration process can be quite costly and time-consuming in terms of workers' hours, audit fees, and fees to investment bankers. Raising funds via an FI can be less expensive, particularly for smaller capital needs or when funds are needed for only a short time period. (Maturities of 270 days or less do not require registration, nor do private placements.)
- Flexible terms: Nonstandard terms can be negotiated with FIs but are difficult to sell to the public. For example, if a borrower can only begin paying interest after two years, he or she would have a difficult time selling bonds to the public.
- Ability to change terms: There is a greater ability to renegotiate terms if necessary. Terms of public issue generally cannot be changed outside of court.
- Privacy: Less information is made public.

How can a depository intermediary (DI) afford to purchase long-term risky direct claims from users of funds and finance these purchases with safe, liquid, short-term, low-denomination deposits? What can go wrong in this process?

DIs can afford to do so because the rate they must pay to attract funds is lower than the rate they can charge on their riskier assets. A lot can go wrong, however, including:

- If the money lent is not repaid, the DI may not be able to repay its depositors on demand (credit and liquidity risk). Diversification of the credit risk is a key way DIs limit credit risk.
- The difference between the rate earned on assets and the rate paid on liabilities is called the Net Interest Margin (NIM). The NIM can turn negative if interest rates rise or if the rates on long-term securities fall below the interest rate risk on short-term securities (after adjusting for risk).
- Because the assets and liabilities are different claims, it is possible for the value of the assets to drop resulting in an insolvent institution (insolvency risk). Because the assets are primarily financial, their value can be quite volatile. As a result, risk management is crucial at today's financial institution.
- DIs attract many savers with a small amount of funds. DIs then invest the bulk of these savings in investments that cannot be immediately liquidated. If the savers lose confidence in the DI, they will seek to withdraw their money, which can precipitate a liquidity crisis and cause insolvency.

Discuss the benefits to funds suppliers of using a financial intermediary asset transformer in place of directly purchasing claims such as stocks or bonds. What is the major disadvantage?

Potential benefits to funds suppliers are as follows:

- Professional risk managers to assess risk of borrower's claim and help decide the correct price to pay.
- Risk reduction via:
 - insurance.
 - additional diversification.
 - more frequent monitoring.
 - additional cushion of FI equity.
 - improved liquidity of funds supplier's claim on FI.
- Denomination intermediation.
- Maturity intermediation.
- The major disadvantage is that you may forego potentially higher returns if you do not purchase the riskier direct claims.

Discuss the major macro benefits of financial intermediaries. What role does the government have in the credit allocation process?

- Money supply transmission: Depository institutions affect the level of money supply growth in the economy. The money supply is increased when the Fed increases money available to banks, but the extent of money supply growth is affected by banks' decisions to lend the increased supply of funds. If the banks do not lend the increased money, the given increase in funds by the Fed will result in only a small change in the total money supply in the economy.
- Credit Allocation: FIs price risk and allocate capital to users who they believe can generate a high enough rate of return to compensate the lender for the risk the lender bears in loaning the money. FIs also monitor the borrower's condition after the loan is made. A well-functioning economy must have sound mechanisms for allocating capital. In capitalist countries, FIs and markets allocate capital to its highest valued uses, thereby maximizing economic growth. The role of government is to ensure disclosure of risks and fair practices of all involved. In communist and some socialist countries, governments allocate capital according to a current political agenda and strong, lasting economic growth is rarely, if ever, seen in these countries. As the text indicates, the government can also channel credit to socially deserving areas such as housing, farms, and small business development.
- Intergenerational wealth transfers and risk shifting: Pension funds and insurance firms allow investors to transfer wealth through time, while avoiding taxation, and/or allow investors the ability to choose which risks in their life they will bear and which they will insure.
- Payment services: The ability to store and quickly move large sums of money (or many small sums) at low cost with little risk encourages greater investment by market participants and, thus, lowers the overall cost of funds in our economy.

What determines the price of financial instruments? Which are riskier, capital market instruments or money market instruments? Why?

The price of any financial instrument is the present value of future cash flows discounted at an appropriate rate. A small change in interest rates causes a large change in present value of distant cash flows. Hence, the prices of long-term capital market instruments are more sensitive to changes in interest rates than prices of short-term instruments. In addition, distant cash flows for stocks are not known with certainty. Changing economic prospects can cause very large changes in current stock values. Money market instruments have predictable cash flows and mature in one year or less, so they are much less risky.

Explain how the credit crunch originating in the mortgage markets hurt financial intermediaries' attempts to use diversification and monitoring to limit the riskiness of their loans and investments while offering more liquid claims to savers.

Financial intermediaries' (FIs) attempts to diversify away from specific risk failed when large portions of the debt markets "seized up" and stopped functioning. At that point, many security prices declined all at once, regardless of historical correlations among security prices. This is a failure of diversification to reduce risk. FIs exploit diversification principles and economies of scale to allow the FI to invest large amounts of money. They also must closely monitor the riskiness of their loans and securities, and many FIs are also regulated by the government to ensure they manage the riskiness of their assets. Some would argue that FIs failed to monitor the riskiness of many of their mortgage investments as well, leading to large numbers of poor investments.
